(57) **ABSTRACT**

A sound producing apparatus with multi-directivity has two or more speakers to produce music or other types of audio sounds. Each of the speakers can produce audio sounds in a certain direction and at least one speaker is steerable so that its sound propagation direction relative to the others can be changed. Furthermore, one or more speakers can produce audio sounds in an adjustable angular range. One or more of the speakers can be dual-mode speakers, each of which can be operated as a wide-angle speaker or a narrow-angle speaker. With multi-directivity, it is possible to play one type of music in one direction and another type of music in another direction to suit the interests of the audience. The apparatus can be a mobile phone, an audio player, a digital or analog recorder/player, or the like.

MULTI-DIRECTIVITY SOUND DEVICE**FIELD OF THE INVENTION**

The present invention relates to a sound device or audio
loudspeaker and, more particularly, to a multi-directivity
sound device.

BACKGROUND OF THE INVENTION

Mobile phones and portable devices can include both the
telecommunication and audiovisual entertaining features.
The audiovisual features may include music playback, video
playback, camcording, gaming, radio, audiovisual telecon-
ferencing, etc. When the mobile phone or the portable device
is used in a placed where two or more persons are present,
sometimes it is desirable to share the audiovisual features
with other people. Sometimes it is desirable to minimize the
spread of audio sounds.

SUMMARY OF THE INVENTION

The present invention provides a sound producing appa-
ratus with multi-directivity. The sound producing apparatus
can be a mobile phone, an audio player, a digital or analog
recorder/player, or the like. The sound producing apparatus
has two or more speakers to produce music or other types of
audio sounds. Each of the speakers can produce audio
sounds in a certain direction and at least one of the speakers
is steerable so that the sound propagation direction of one
speaker relative to the others can be changed. Furthermore,
one or more speakers can produce audio sounds in an
angular range and the angular range of at least one of the
speakers is adjustable. For example, one or more of the
speakers are dual-mode speakers, each of which can be
operated as a wide-angle speaker or a narrow-angle speaker.

Thus, the first aspect of the present invention is an
apparatus, which comprises:

- a plurality of sound producing units;
- a steering control; and

a signal source to provide signals to the sound producing
units for producing audio sounds, wherein each of the sound
producing units is arranged to produce the audio sounds in
a sound propagation direction and wherein the steering
control is arranged to change the sound propagation direc-
tion of one or more sound producing units.

According to various embodiments of the present inven-
tion, each of the sound producing units is configured to
produce the audio sounds in an angular range, and the
steering control is arranged to change to angular range of at
least one of the sound producing units.

According to various embodiments of the present inven-
tion, the audio sounds produced on different sound produc-
ing units can be the same or different type or genre. The
sounds can be stereo.

The second aspect of the present invention is a method,
which comprises:

selecting one or more of a plurality of sound producing
units in a sound producing device, wherein each of the sound
producing units is arranged to produce audio sounds in a
sound propagation direction; and

adjusting the sound propagation direction of at least one
of the sound producing units relative to the sound propaga-
tion direction of another sound producing unit.

According to various embodiments of the present inven-
tion, each of the sound producing units is configured to
produce the audio sounds in an angular range, and the

2

method further comprises adjusting the angular range of at
least one of the sound producing units.

The third aspect of the present invention is an apparatus,
which comprises:

means for producing audio sounds comprising a plurality
of sound producing units, each sound producing unit
arranged to produce the audio sounds in a sound propagation
direction;

means for selecting the sound producing units; and

means for controlling the sound propagation direction of
at least one selected sound producing unit.

According to various embodiments of the present inven-
tion, each of the sound producing units is configured to
produce the audio sounds in an angular range, and the
apparatus further comprises means for adjusting the angular
range of at least one of the sound producing units.

The present invention will become apparent upon reading
the description taken in conjunction with the drawings as
shown in FIGS. 1 to 7.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows a portable device, according to one embodi-
ment of the present invention.

FIG. 2a shows one of the sound steering features of the
present invention.

FIG. 2b shows another one of the sound steering features
of the present invention.

FIG. 3a shows a sound producing unit having two sub-
modules, according to one embodiment of the present inven-
tion.

FIG. 3b shows one example of steering the sounds from
the two sub-modules.

FIG. 3c shows another example of steering the sounds
from the two sub-modules.

FIG. 3d shows a different example of steering the sound
from the two sub-modules.

FIG. 4a shows an array of transducers used to produce
sound in one sound producing unit.

FIG. 4b shows the steering components for steering the
transducer array.

FIG. 4c shows an example of steering the transducer
array.

FIG. 5 shows an example of audio loudspeaker that can be
used as a sound producing unit.

FIG. 6 shows the details of the audio loudspeaker of FIG.
5.

FIG. 7 illustrates an exemplary user-interface.

**DETAILED DESCRIPTION OF THE
DISCLOSURE**

The present invention provides a sound producing appa-
ratus with multi-directivity. The sound producing apparatus
has two or more sound producing units to achieve multi-
directivity. In particular, each of the sound producing units
is arranged to produce audio sounds in a certain sound
propagation direction. A steering control is arranged such
that the sound propagation direction of one sound producing
unit relative to the other can be changed. When the sound
apparatus is used in a portable device such as a portable
music player or a mobile phone, the sound producing
apparatus can be used for telecommunication purposes, as
well as entertainment purposes.

When the sound producing apparatus is used in a placed
where two or more persons present, sometime it is desirable
to share the audiovisual features with other people. Some-

3

time it is desirable to minimize the spread of audio sounds. With a sound producing apparatus with multi-directivity, it is possible to play one type of music in one direction and another type of music in another direction to suit the interests of the audience.

FIG. 1 shows a sound producing apparatus with multi-directivity, according to one embodiment of the present invention. As shown in FIG. 1, the apparatus 10 can be used as a telecommunication device and as an entertainment device with two or more audio loudspeakers 21, 22, 23 and 24. Each of the audio loudspeakers is arranged to be an independent sound producing unit in that each audio loudspeaker can be selected to produce music or other type of audible sound, independent of the other. It is possible to include an antenna 82 to transmit or receive telecommunication signals through a transceiver 80. Like a mobile terminal, the apparatus 10 has a microphone 72 to allow a user to speak to another party. The user can use any one of the loudspeakers to listen to a conversation, a radio broadcast and a recording, for example. When the user wants to listen to a radio broadcast, the user can select to receive broadcast signals through the antenna 82 and the transceiver 80. The broadcast signals are processed by a signal processor 50 into sound data to be played out in any one of the loudspeakers 21-24. Alternatively, the sound data can be stored in a buffer 44. The apparatus 10 can be arranged to receive a memory unit which stores different sound data so that the stored sound data can be retrieved and played out in a different loudspeaker. The apparatus 10 has a speaker selector 40 for channeling one or more sources of sound data to different loudspeakers, for example. The apparatus 10 has a display 70 for displaying information. For example, the display 70 can be used to list the different sound data files available in the memory 46 and the buffer 44. Based on the displayed list, the user to select what sound data file or files to be played out through the user interface 60. Furthermore, the user can select which loudspeaker or loudspeakers to be used at any time.

According to various embodiments of the present invention, one or more of the loudspeakers 21-24 are steerable, mechanically and/or acoustically. As shown in FIG. 1, when the loudspeakers are used to produce audio sounds, the produced audio sounds have different sound propagation directions. For example, loudspeaker 22 produces audio sounds in direction 122, loudspeaker 23 produces audio sounds in direction 123, and loudspeaker 24 produces audio sounds in direction 124. At a certain distance, the sounds from loudspeaker 23 may mix those from loudspeaker 24. If these loudspeakers are selected to produce different types of music, sound or voice, for example, the sound mixing may not be desirable. Thus, it is advantageous and desirable to steer one or both sound sources to different directions by a speaker control 30. For example, the loudspeaker 23 is mechanically moved to change the sound propagation direction 123, as shown in FIG. 2a. In this embodiment, the speaker control 30 comprises an electro-mechanical movement means, such as a motor, a solenoid with a shaft or the like, to push the loudspeaker 23 away from its original position. The speaker control 30 may comprise a mechanical component, such as a rod, a turn-knob or the like so as to allow a user to adjust the sound propagation direction manually. The speaker control 30 may comprise a sound reflecting surface 32 the orientation of which can be adjusted in order to change the sound propagation direction as shown in FIG. 2b. The sound reflecting surface 32 can be adjusted independently or in combination with the steering of the speaker 24. Furthermore, the sound reflecting surface 32 can

4

be flat or curved, and it can also be flexible so as to adjust the angular spread or the propagation pattern of the audio sounds.

In another embodiment of the present invention, a loudspeaker includes two or more sub-units or sub-speakers. For example, the loudspeaker 23 has two separate loudspeakers 23R and 23L to produce audio sounds along the sound propagation direction 123. The loudspeakers 23R and 23L are connected to the speaker control 30 so that they can be steered relative to each other as shown in FIG. 3a. As shown in FIG. 3b, the loudspeakers 23R and 23L are steered toward the same direction to change the sound propagation direction 123. As shown in FIG. 3c, the loudspeakers 23R and 23L are steered toward each other. As such, the overall sound propagation direction 123 remains unchanged, but the sound spreading is reduced. As shown in FIG. 3d, the loudspeakers 23R and 23L are steered away from each other. As such, the overall sound propagation direction 123 remains unchanged, but the sound spreading is increased. Thus, with two or more sub-speakers, it is possible to change the overall sound propagation direction, as well as the sound-spreading angular range.

In another embodiment of the present invention, one or more of the loudspeakers can be a steerable array. As shown in FIG. 4a, the loudspeaker 23 is made of a plurality of vibration elements 230 arranged in a two-dimensional array 200. Each of the vibration elements 230 is connected to a transducer 330, and the transducers 330 are connected to a speaker control 30', as shown in FIG. 4b. The array of vibration elements 230 can be utilized in two ways. In one embodiment of the present invention, the vibration elements 230 are individually movable by the corresponding transducers 330. The vibration elements 230 can be arranged to move toward each other to change to sound-propagation angle as shown in FIG. 4c. These vibration elements can be steered away from each other, as shown in FIG. 3d, or steered toward the same direction as shown in FIG. 3c. In a different embodiment, the vibration elements 230 form a phase array such that the propagation direction or the propagation angle can be changed by adjusting the relative phase among the vibration elements 230. In this embodiment, the speaker control 30' is also used to adjust the phase of the vibrations in each of the vibration elements 230.

In yet another embodiment of the present invention, one or more of the loudspeakers can be a dual-mode sound producing unit, as shown in FIGS. 5 and 6. A dual-mode sound producing unit 20, as shown in FIGS. 5 and 6, includes a vibrating structural component (also called transducer) such as a membrane, a clamped-clamped beam, or a cantilever, or an array of such structures, which can be excited by a specific exciting signal so that it produces audible sound waves in the 20 Hz to 20 kHz range, for example. The vibration structure component can also be excited in a higher frequency range, such as an ultrasonic frequency range (about 30 kHz-120 kHz). At this frequency range, the transducer or transducer array can produce a directional beam of ultrasonic waves. Due to the non-linear interaction of ultrasonic waves in the air, the directional beam of ultrasonic waves becomes audible after traversing a distance. According to the present invention, the acoustic component that produces the audible sound in a conventional way is the same acoustic component that, when excited by ultrasound waves, produces substantially directional sound after the ultrasonic waves traverse a specific distance.

FIG. 5 is a cross sectional view of the dual-mode sound producing unit 20, showing a transducer 430 coupled to a

5

cantilever diaphragm **420** on the substrate **410**. As shown, the cantilever diaphragm **420** comprises a plurality of low temperature oxide (LTO) layers **442**, **444**, **446** on top of a silicon nitride layer **460**. Below the silicon nitride layer **460**, there is a thermal oxide layer **470**, followed by a number of other layers. The transducer **430** comprises a piezoelectric (PZT) layer **450** sandwiched between two LTO layers **442** and **444**. On top of the transducer **430** is an electrode layer **440**, while the bottom electrode layer **448** is below the PZT layer **450**.

Another example of the dual-mode sound producing units, according to a different embodiment of the present invention, is shown in FIG. 6. As shown in FIG. 6, the sound producing unit **20** has a transducer **530** coupled to a low frequency acoustic component **520**. A thin section of a silicon substrate **580** is used as a diaphragm of the low frequency acoustic component. **520**. On top of the low frequency acoustic component **520**, the transducer **530** having a piezoelectric (PZT) layer **550**, and a polynitride layer **543** is provided. A top electrode layer **540** and a bottom electrode layer **548** are used to provide an excitation electrical signal in order to induce the movement of the PZT layer **550**. The transducer **530** is coupled to the low frequency acoustic component **520** via a plurality of layers, including an LTO layer **546**, a silicon nitride layer **560** and silicon dioxide layer **570**.

With the dual-mode sound producing unit **20**, the diaphragm can be excited by a specific exciting signal so that it produces audible sound waves in the 20 Hz to 20 kHz range, for example. When the diaphragm is excited in a higher frequency range, such as an ultrasonic frequency range (about 30 kHz-120 kHz), the waves (carrier waves modulated by audio signal) in the near field are in the ultrasonic frequency and, therefore, not audible. As the waves travel through air, the carrier frequencies are lost due to the non-linear interaction of ultrasonic waves in the air. The envelope of the modulated waves produces audible sound while retaining at least part of the directivity of the wave pattern. As such, the audible sound produced by a device is largely confined to a small number of people. Thus, the sound producing unit **20** can be used in two modes, one for producing audio sounds in a wider angle and one for producing audio sounds in a narrower angle.

As illustrated in various embodiments, the present invention provides an apparatus, which comprises a plurality of sound producing units; a steering control; and a signal source for providing signals to the sound producing units for producing audio sounds, wherein each of the sound producing units is arranged to produce the audio sounds in a sound propagation direction and wherein the steering control is arranged to change the sound propagation direction of one or more sound producing units. In one embodiment of the present invention, each of the sound producing units is configured to produce the audio sounds in an angular range, and wherein the steering control is arranged to change the angular range of at least one of the sound producing units. In order to allow a user to use the apparatus **10** as a versatile sound producing device, the user interface **60** (see FIG. 1) may comprise an information input console **62** and a software program **64**, as shown in FIG. 7. For example, the input console **62** comprises a program selection module to allow a user to choose the music/audio programs to be played; a mode selection module to allow a user to select the speaker mode of selected speakers (e.g. wide-angle sound mode, narrow-angle sound mode, stereo sound mode, etc.); a steering control to allow a user to selectively change the sound propagation direction of each selected speaker; and a

6

volume control to allow a user to selectively adjust the audio level of each selected speaker. The input console **62** can be a part of a keyboard of the apparatus **10**. The input console **62** can be presented as a touch screen displayed on the display **70** (see FIG. 1), for example. On the display **70**, it is possible to provide a play-list to show a user what audio programs are available on the apparatus **10**. The information input console **62** is operatively connected to a software program **64** which comprises programming codes to compile the input information into control data provided to the signal processor **50** (FIG. 1). The signal processor **50** can be an ASIC chip, for example. The software program **62** can be implemented on a computer readable storage medium. The software program **62** can be upgraded or changed to accommodate the audio features of the apparatus **10**, for example.

In sum, the present invention provides an apparatus, which has a plurality of sound producing units; a steering control; and a signal source to provide signals to the sound producing units for producing audio sounds, wherein each of the sound producing units is arranged to produce the audio sounds in a sound propagation direction and wherein the steering control is arranged to change the sound propagation direction of one or more sound producing units.

According to various embodiments of the present invention, each of the sound producing units is configured to produce the audio sounds in an angular range, and the steering control is arranged to change to angular range of at least one of the sound producing units.

According to various embodiments of the present invention, the audio sounds produced on different sound producing units can be the same or different type or genre. The sounds can be stereo.

In one embodiment of the present invention, a sound producing unit comprises two loudspeakers, and each loudspeaker is steerable to change the sound propagation direction relative to the other loudspeaker.

In another embodiment of the present invention, a sound producing unit comprises an array of vibration elements, and the vibration elements can be arranged to change the sound propagation direction of said one sound producing unit.

In yet another embodiment of the present invention, a sound producing unit comprises an array of vibration elements, and the vibration elements are arranged to change the sound angular range of said one sound producing unit.

In a different embodiment, at least one of sound producing units is a dual-mode sound producing module, which is excitable in a first mode by an exciting signal in an audio frequency range and a second mode by an exciting signal in an ultrasound frequency range.

According to various embodiments of the present invention, the steering control comprises an electro-mechanical movement module, a mechanical component, or a reflecting surface for changing orientation of one or more sound producing units.

According to different embodiments of the present invention, the sound producing unit comprises an array of vibration elements, and the steering control comprises one or more transducers arranged to move the vibration elements for changing the sound propagation direction and/or the sound angular range of the sound producing unit.

According to various embodiments of the present invention, the apparatus also has a user interface comprising selectable items for allowing a user to select the sound producing units and the sound propagation direction of one or more sound producing units. Part or the entire user interface can be implemented as a touch screen on a display.

Various features on the user interface can be carried out by a software program embedded in a computer readable storage medium.

According to various embodiments of the present invention, the audio data for producing the audio sounds can be stored in a fixed memory or a removable memory unit.

The apparatus can be a wireless device which has a receiver arranged to receive audio data for producing the signals.

The present invention also provides a method for producing sounds in a sound producing apparatus, and the method comprises: selecting one or more of a plurality of sound producing units in a sound producing device, wherein each of the sound producing units is arranged to produce audio sounds in a sound propagation direction; and adjusting the sound propagation direction of at least one of the sound producing units relative to the sound propagation direction of another sound producing unit.

According to various embodiments of the present invention, each of the sound producing units is configured to produce the audio sounds in an angular range, and the method further comprises adjusting the angular range of at least one of the sound producing units.

In general, the present invention provides an apparatus comprising means for producing audio sounds comprising a plurality of sound producing units, each sound producing unit arranged to produce the audio sounds in a sound propagation direction; means for selecting the sound producing units; and means for controlling the sound propagation direction of at least one selected sound producing unit.

According to various embodiments of the present invention, each of the sound producing units is configured to produce the audio sounds in an angular range, and the apparatus further comprises means for adjusting the angular range of at least one of the sound producing units.

The apparatus, according to various embodiments of the present invention, can be a communication device, such as a mobile phone, or a standalone entertainment device, such as an audio/video player. The apparatus can also be a mixed use device such as a gaming console.

Thus, although the present invention has been described with respect to one or more embodiments thereof, it will be understood by those skilled in the art that the foregoing and various other changes, omissions and deviations in the form and detail thereof may be made without departing from the scope of this invention.

What is claimed is:

1. An apparatus, comprising:

a plurality of sound producing units comprising at least a first sound producing unit and a second sound producing unit spaced from the first sound producing unit within the apparatus, wherein the first sound producing unit and the second sound producing unit are independent sound producing units which can produce audible sounds independent of each other;

a steering control to adjust a sound propagation direction of at least the first sound producing unit; and

a signal source to provide audio signals to the sound producing units, wherein the first sound producing unit is configured to produce a first audible sound in a first sound propagation direction and the second sound producing unit is configured to produce a second audible sound in a second sound propagation direction, wherein the first audible sound and the second audible sound are from separate sound producing units, wherein at least the first sound propagation direction of the first sound producing unit is independently adjust-

able based on the steering control, wherein the first sound propagation direction is changed relative to the second sound propagation direction, and where the apparatus is a portable electronic device.

2. The apparatus of claim 1, wherein each of the sound producing units is configured to produce the audio sounds in an angular range, and wherein the steering control is arranged to change to angular range of the first sound producing unit.

3. The apparatus of claim 1, wherein the audio sounds produced on at least one of the sound producing units are different from the audio sounds produced on the other of the sound producing units.

4. The apparatus of claim 1, wherein two or more of the sound producing units are arranged to produce stereo audio sounds.

5. The apparatus of claim 1, wherein the steering control comprises an electro-mechanical movement module for changing orientation of the first sound producing unit.

6. The apparatus of claim 1, wherein the steering control comprises a mechanical component for changing orientation of the first sound producing unit.

7. The apparatus of claim 1, further comprising:

a user interface comprising a display of selectable items for allowing a user to select the sound producing units and the sound propagation direction of one or more sound producing units.

8. The apparatus of claim 7, further comprising:

a processor arranged to effect the sound propagation direction selected by the user; and

a computer readable storage medium having embedded programming codes to provide information to the processor indicative of selection made by the user.

9. The apparatus of claim 1, further comprising:

a sound data storage comprising a removable memory unit and arranged to provide audio data to the signal source for producing the signals.

10. The apparatus of claim 1, further comprising: a receiver arranged to receive audio data for producing the signals.

11. The apparatus according to claim 1, wherein the first sound producing unit and the second sound producing unit are arranged to produce audible sound waves in a range of 20 Hz to 20 KHz.

12. The apparatus according to claim 1, wherein the first sound producing unit and the second sound producing unit are configured to be excited in an ultrasonic frequency range of 30 kHz to 120 kHz so as to produce ultrasonic waves which become audible after traversing a distance due to non-linear interaction of the ultrasonic waves in air.

13. A method, comprising:

selecting one or more of a plurality of sound producing units in a sound producing device, wherein at least a first sound producing unit and a second sound producing unit are independent sound producing units which can produce audio sounds independent of each other and in different sound propagation directions, the audio sounds being from separate sound producing units; and adjusting the sound propagation direction of at least one of the sound producing units independently of another one of the sound producing units,

wherein the sound propagation direction of the at least one sound producing unit is changed relative to a sound propagation direction of the another one of the sound producing units, and

wherein the sound producing device comprises a portable electronic device.

9

14. The method of claim 13, wherein each of the sound producing units is configured to produce the audio sounds in an angular range, said method further comprising: adjusting the angular range of at least one of the sound producing units.

15. The method according to claim 13, wherein each of the sound producing units is arranged to produce audible sound waves in a range of 20 Hz to 20 KHz.

16. The method according to claim 13, wherein the audio sounds produced on at least one of the sound producing units are different from the audio sounds produced on the other of the sound producing units.

17. The method according to claim 13, wherein the first sound producing unit and the second sound producing unit are configured to be excited in an ultrasonic frequency range of 30 kHz to 120 kHz so as to produce ultrasonic waves which become audible after traversing a distance due to non-linear interaction of the ultrasonic waves in air.

18. A non-transitory computer readable medium having programming codes embedded therein, the programming codes configured to, when executed by a processor:

select one or more of a plurality of sound producing units in a sound producing device, wherein at least a first sound producing unit and a second sound producing unit are independent sound producing units which can

10

produce audio sounds independent of each other and in different sound propagation directions, the audio sounds being from separate sound producing units; and adjust the sound propagation direction of at least one of the sound producing units independently of another one of the sound producing units, wherein the sound propagation direction of the at least one sound producing unit is changed relative to a sound propagation direction of the another one of the sound producing units, and wherein the sound producing device comprises a portable electronic device.

19. The non-transitory computer readable medium of claim 18, wherein each of the sound producing units is configured to produce the audio sounds in an angular range, the programming codes further configured to adjust the angular range of at least one of the sound producing units.

20. The computer program product according to claim 18, wherein the first sound producing unit and the second sound producing unit are configured to be excited in an ultrasonic frequency range of 30 kHz to 120 kHz so as to produce ultrasonic waves which become audible after traversing a distance due to non-linear interaction of the ultrasonic waves in air.
